DEVICE TEST

1, Explain behaviour of hub device

it is used to connect multiple device,layer 1 device.
used to broadcast.

- when hub receives data ->it sends to all connected devices
- all device receives data and corresponding MAC address only open and read, rest should drop it.
- when 2devices are sending data simultaneously it will clash and data will be lost. this is called collision
- drawbacks of HUB == broadcast and collision

2, Explain behaviour of switch device

it is used to connect multiple network device,layer 2 ,contains broadcast and unicast

- when data sent to SWITCH ->it will do address learning
- MAC table will create, in that SMAC and S port no stored then checks for DMAC → if DMAC is there in table → do unicast..... is not there in DMAC → do broadcast this is called address learning
- MAC table's time limit is 5min

3, Explain behaviour of router device

it is used to connect different network device, layer 3
used to break broadcast domain

- when ROUTER receives data → Dip will check route in routing table.
- if it's there-> sends to corresponding interface number ex(e0,e1)
- if not there → drop

Assignig IP in ROUTER

- while assigning ip in router → it will automatically do 3 things in routing table
- (n/w id, prefix length, interface name) this is called Direcctly connected devices
-
